

Isolation effects across starting populations — deterministic density model

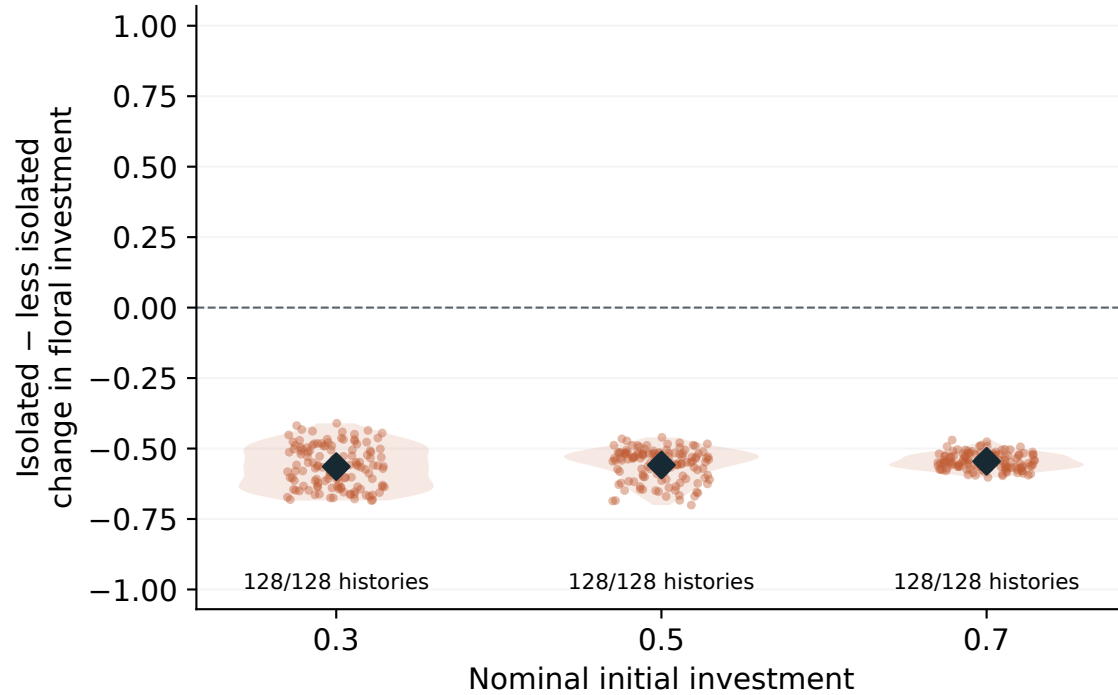

A. Natural histories

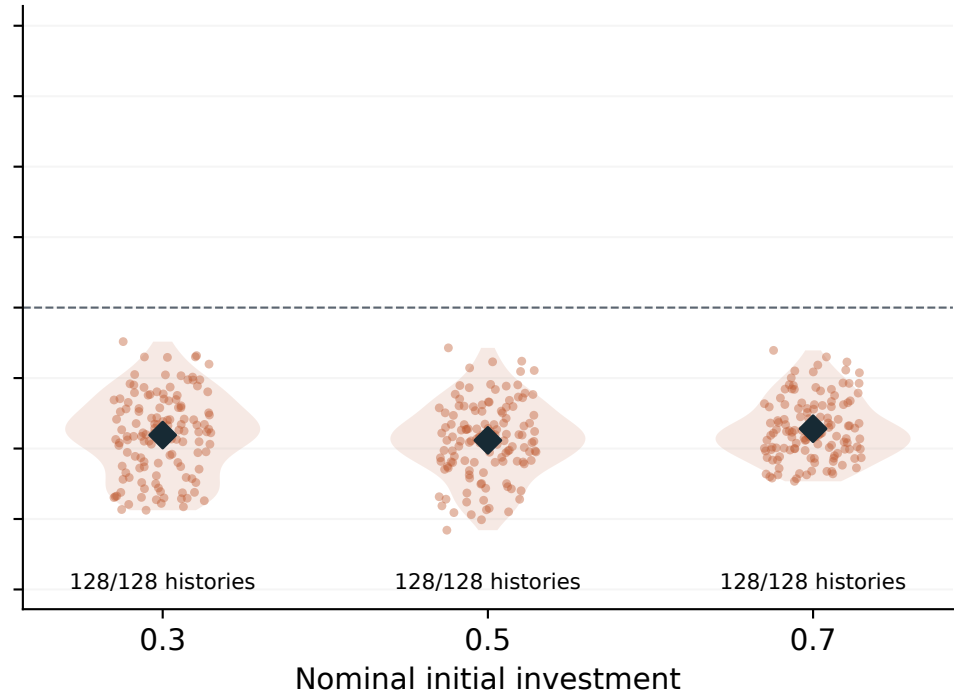

B. Richness matched

C. Eight visitor histories pooled

D. Larger plant population

Each dot: one visitor history, averaged over all demographic repeats; incomplete histories are omitted and counted.
 Diamonds: joint-survivor conditional means; bars: 95% history-bootstrap intervals. Violin widths show relative density.
 Positive / negative values mean greater / smaller investment change under isolation. Identical scales in all panels.
